The Simple Effective Interaction (SEI)

The finite range simple effective interaction was initially proposed by Behera and collaborators and has the following explicit form for a Yukawa finite range form factor (SEI-Y),

\[ V_{\text{eff}} = t_0 (1 + x_0 P_{\sigma}) \delta(\vec{r}) + \frac{t_3}{6} (1 + x_3 P_{\sigma}) \left( \frac{\rho(\vec{R})}{1 + b\rho(\vec{R})} \right)^\gamma \delta(\vec{r}) + (W + BP_{\sigma} - HP_{\tau} - MP_{\sigma} P_{\tau}) \frac{e^{-r/\alpha}}{r/\alpha} \text{Spin-orbit part} \]

where a zero-range spin-orbit (SO) interaction depending on a strength parameter \( W_0 \) is taken to deal with finite nuclei. The SEI in Eq.(??) has 12 parameters in total, namely, \( \alpha, \gamma, b, x_0, x_3, t_0, t_3, W, B, H, \) and \( M \) plus the spin-orbit strength parameter \( W_0 \), which enters in the description of finite nuclei.

Nine of these twelve parameters are fitted to reproduce empirical constraints and microscopical results in nuclear and neutron matter.
\[ H_Y(\rho_n, \rho_p) = \frac{3\hbar^2}{10m} (k_n^2 \rho_n + k_p^2 \rho_p) + \frac{\varepsilon_l}{2\rho_0} (\rho_n^2 + \rho_p^2) + \frac{\varepsilon_{ul}}{\rho_0} \rho_n \rho_p \]

\[
+ \left[ \frac{\varepsilon'_\gamma}{2\rho_0^{\gamma+1}} (\rho_n^2 + \rho_p^2) + \frac{\varepsilon''_\gamma}{\rho_0^{\gamma+1}} \rho_n \rho_p \right] \left( \frac{\rho(R)}{1 + b\rho(R)} \right)^\gamma
\]

\[
+ \frac{\varepsilon'_{\text{ex}}}{2\rho_0} \rho_n^2 \left[ \left( \frac{3\Lambda^6}{32k_n^6} + \frac{9\Lambda^4}{8k_n^4} \right) \ln \left( 1 + \frac{4k_n^2}{\Lambda^2} \right) - \frac{3\Lambda^4}{8k_n^4} + \frac{9\Lambda^2}{4k_n^2} - \frac{3\Lambda^3}{k_n^3} \tan^{-1} \left( \frac{2k_n}{\Lambda} \right) \right]
\]

\[
+ \frac{\varepsilon'_{\text{ex}}}{2\rho_0} \rho_p^2 \left[ \left( \frac{3\Lambda^6}{32k_p^6} + \frac{9\Lambda^4}{8k_p^4} \right) \ln \left( 1 + \frac{4k_p^2}{\Lambda^2} \right) - \frac{3\Lambda^4}{8k_p^4} + \frac{9\Lambda^2}{4k_p^2} - \frac{3\Lambda^3}{k_p^3} \tan^{-1} \left( \frac{2k_p}{\Lambda} \right) \right]
\]

\[
+ \frac{\varepsilon''_{\text{ex}}}{\rho_0} \rho_n \rho_p \left[ \frac{3}{32} \left[ \left( \frac{\Lambda^6}{k_n^3k_p^3} + \frac{6\Lambda^4}{k_n^3k_p^3} + \frac{6\Lambda^4}{k_n^3k_p^3} \right) - \frac{3\Lambda^2(k_p^2 - k_n^2)^2}{k_n^3k_p^3} \right] \right]
\]

\[ \times \ln \left[ \frac{\Lambda^2 + (k_n + k_p)^2}{\Lambda^2 + (k_n - k_p)^2} \right]
\]

\[
+ \frac{\varepsilon''_{\text{ex}}}{\rho_0} \rho_n \rho_p \left[ \frac{3}{2} \left( \frac{\Lambda^3}{k_n^3} - \frac{\Lambda^3}{k_p^3} \right) \tan^{-1} \left( \frac{k_p - k_n}{\Lambda} \right) - \frac{3}{2} \left( \frac{\Lambda^3}{k_p^3} + \frac{\Lambda^3}{k_n^3} \right) \tan^{-1} \left( \frac{k_n + k_p}{\Lambda} \right) \right]
\]

\[
+ \frac{\varepsilon''_{\text{ex}}}{\rho_0} \rho_n \rho_p \left[ \frac{9}{8} \left( \frac{\Lambda^2}{k_p^2} + \frac{\Lambda^2}{k_n^2} \right) - \frac{3}{8} \frac{\Lambda^4}{k_n^2k_p^2} \right]
\]
Fitting protocol

- The symmetric nuclear matter (SNM) requires only the following three combinations of the strength parameters,

\[
\left( \frac{\varepsilon^l_0 + \varepsilon^u_0}{2} \right) = \varepsilon_0, \quad \left( \frac{\varepsilon^l_\gamma + \varepsilon^u_\gamma}{2} \right) = \varepsilon_\gamma, \quad \left( \frac{\varepsilon^l_{ex} + \varepsilon^u_{ex}}{2} \right) = \varepsilon_{ex},
\]

which together with \( \gamma, b \) and \( \alpha \) constitute the six parameters for the SNM. For a given value of the exponent \( \gamma \), which characterizes as the stiffness parameter and determines the incompressibility.

- It is demanded that the nuclear mean-field in symmetric nuclear matter at saturation vanished for a kinetic energy of incident nucleon of 300 MeV. This constraint allows to determine, for a given value of \( \gamma \), the strength of the exchange energy, \( \varepsilon_{ex} \), and the range of the form factor \( \alpha \).

- The parameter \( b \) is determined to avoid the supra-luminous behaviour.

- The two remaining parameters, \( \varepsilon_0 \) and \( \varepsilon_\gamma \) are obtained from given saturation conditions. (density nd energy per baryon)
• The splitting of the exchange strength is decided to be $\varepsilon_{\text{ex}}^l = 2\varepsilon_{\text{ex}}^{ul}/3$, which ensures that the entropy in pure neutron matter does not exceed that of symmetric nuclear matter.

• The splitting of the parameters $\varepsilon_0$ and $\varepsilon_\gamma$ is decided from the value of the symmetry energy and its slope.

• The characteristic slope of the symmetry energy is fixed from the condition that the asymmetric contribution to the nucleonic part of the energy density in charge neutral beta-stable stellar matter $npe\mu$ is maximal.

• One of the two free parameters, $x_0$, is fixed from the spin-up and spin-down splitting of the effective mass in polarized neutron matter.

• Finally the parameter $t_0$ and the spin-orbit strength $W_0$ are determined from calculations in finite nuclei.

Finite nuclei

\[ H = \frac{\hbar^2}{2M}(\tau_0^n + \tau_0^p) + H_{\text{zero}} + H_{\text{Nucl}} + H_{\text{exch},0} + H_{\text{exch},2} + H_{\text{SO}} + H_{\text{Coul}}. \]

\[ H_{\text{exch},2}(\vec{R}) = \sum_q \frac{\hbar^2}{2m}(f_q - 1)(\tau_q - \frac{3}{5} k_q \rho_q - \frac{1}{4} \nabla^2 \rho_q) \]

\[ + k_q f_q' \left( \frac{1}{27} \frac{(\nabla \rho_q)^2}{\rho_q} - \frac{1}{36} \nabla^2 \rho_q \right), \]

\[ h_q \Phi_i = \varepsilon_i \Phi_i \]

where,

\[ h_q = -\nabla \frac{\hbar^2}{2m^*_q(\vec{R})} \nabla + U_q(\vec{R}) - iW_q(\vec{R})[\nabla \times \vec{\sigma}], \]

with

\[ \frac{\hbar^2}{2m^*_q(\vec{R})} = \frac{\partial E}{\partial \tau_q(\vec{R})}, \quad U_q(\vec{R}) = \frac{\partial E}{\partial \rho_q(\vec{R})}, \quad W_q(\vec{R}) = \frac{\partial E}{\partial J_q(\vec{R})}. \]

\[ \Delta R_{CH} = 0.01549 \quad \Delta R_{CH} = 0.01549 \quad \Delta R_{CH} = 0.01516 \]
\begin{itemize}
\item[(a)] $R_{1.4}$ of 1.4 $M_0$ neutron stars and (b) Radii $R_{1.6}$ of 1.6 $M_0$ neutron stars versus the slope of the incompressibility $K_0'$ obtained using different EoS of SEI-Y having $\gamma=1/3$, 1/2, and 2/3.
\end{itemize}
Neutron star merger and incompressibility of ANM

(a) $K(\rho, \delta)$ as a function of density in NSM for the SEI-Y$(\gamma = 1/3)$, SEI-Y$(\gamma = 1/2)$, and SEI-Y$(\gamma = 2/3)$ EoS, (b) $K_{\text{max}}$ as a function of the compactness of the heaviest NS for the three EoS of SEI-Y. Green diamonds are the 66 EoS results taken from A.Perego et al., Phys.Rev.Lett 129, 032701.
Sound speed in Neutron Star Matter

(a) Speed of sound in NSM as a function density for the three EoS corresponding to $\gamma = 1/3, 1/2, \text{and} 2/3$ of SEI-Y. (b) Speed of sound as a function of pressure at density $(1.85\rho_0)$ in NSM for SEI-Y $1/2$ and $2/3$ EoS compared with the results of Bauswein et al. In panels (c), (d) and (e) the square speed of sound at the central densities of $1.8M_\odot$, $1.6M_\odot$ and $1.4M_\odot$
Gravitational redshift (I)

The gravitational redshift of a signal from the star surface is

\[ Z_{\text{surf}} = \left(1 - \frac{2GM}{c^2 R}\right)^{-1/2} - 1 \]

Gravitational redshift at the neutron star surface as a function of the stellar gravitational mass for the SEI-Y (\(\gamma = 1/2\)) and SEI-Y (\(\gamma = 2/3\)) EoSs. The extracted ranges for the three NSs, RBS 1223, RX J0720.4-3125, and RX J1856.5-3754 are shown in different shades.
Gravitational redshift (II)

$Z_{\text{surf}}$ as a function of $\eta$ for $1.8 \, M_0$, $1.6 \, M_0$, and $1.4 \, M_0$ NS for SEI-Y ($\gamma = 1/2$) and SEI-Y ($\gamma = 2/3$) EoSs. Shaded region is the constrained value of $\eta$ for PREX II [Blue], RCNP [magenta], and $S\pi$RIT [yellow] [?]. The green diamonds are the data for the 44-EoSs of N. Alam et al, Phys.Rev.C94,052801(2016).
Gravitational redshift (III)

(a) Neutron star masses, (b) Neutron star radius (c) $Z_{\text{surf}}$ corresponding to central densities of $\rho_0$, $2\rho_0$, $3\rho_0$, $4\rho_0$, and $6\rho_0$ as a function of L.
