Nature's Fission Fragment Distribution

Monday 16 June 2025 14:45 (15 minutes)

The nuclear mechanism responsible for roughly half of the heavy-elements ($Z > 30$) abundances in our Solar system—the rapid neutron capture (r) process—was long thought to produce a “universal” abundance pattern. However, recent studies have challenged r -process universality by identifying significant variations between the elemental abundances patterns of metal-poor ($[\text{Fe}/\text{H}] < -1.0$), r -process-enhanced stars. In particular, r -process-rich ($[\text{Eu}/\text{Fe}] > +0.3$) stars show a signature that may possibly only be explained by fission. In this work, we construct a method of decomposing stellar abundance patterns into a basis set of patterns from which each star can be constructed as a linear combination, akin to a principal component decomposition. We use this method to uncover the underlying signature that is present in the r -process-rich stars in order to derive an empirical record of fission in the r -process. This talk will present the “pure” fission pattern is that is recovered from these metal-poor stars.
